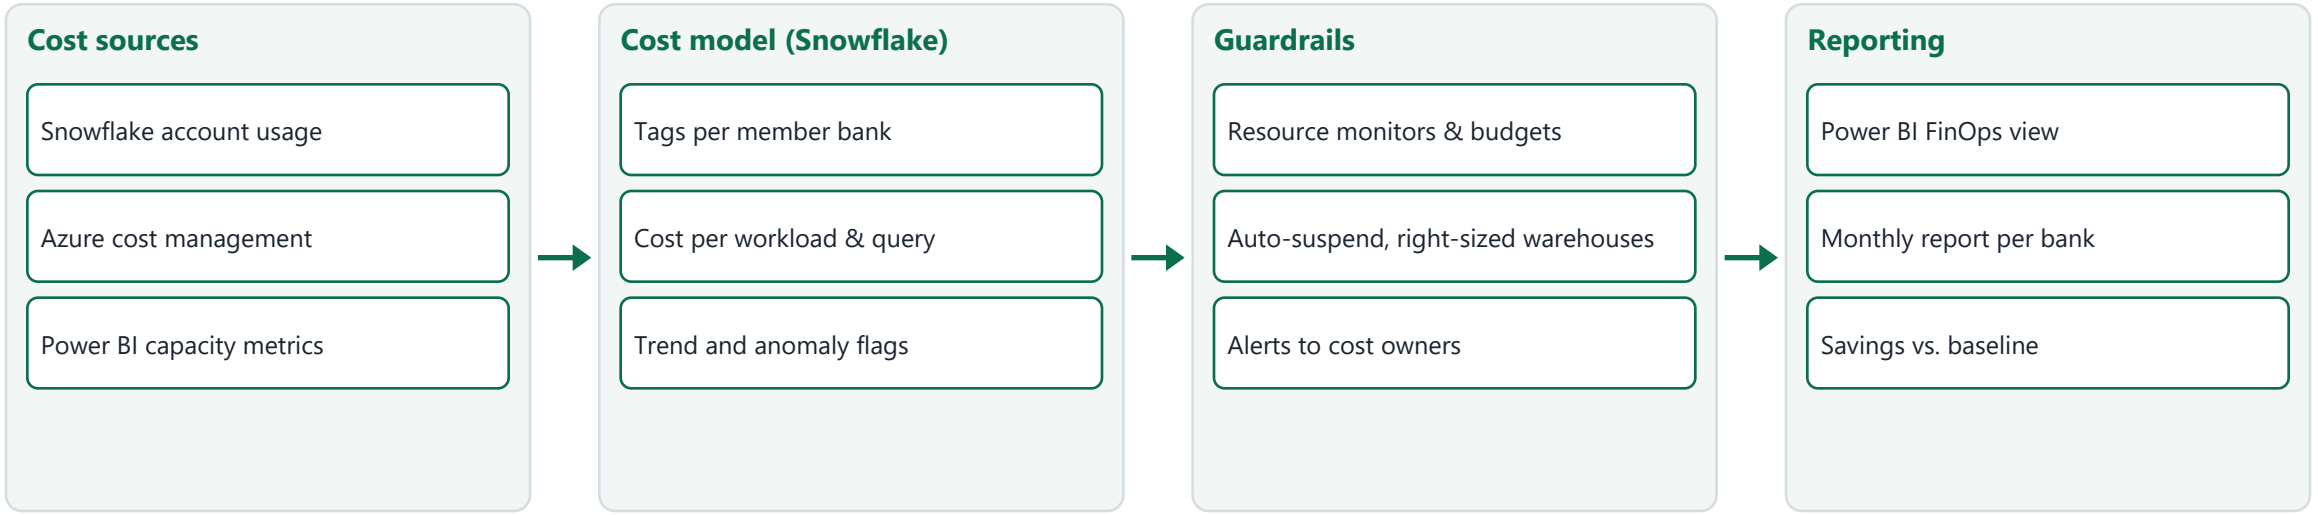
Savings Banks Group (Säästöpankkiryhmä)

Tech & architecture slides for the Savings Banks Group deck

Two slides for deck-writer to insert after the answer-first slide

Cost visibility per member bank and workload, with guardrails inside your own Snowflake and Azure

- Snowflake usage, Azure cost data and Power BI capacity are combined in one cost model, tagged by member bank and workload. Guardrails stop runaway spend before the invoice.
- Everything runs in your tenant in the EU. No data goes to non-European AI toolchains.



Pipelines tied to non-European AI toolchains are inventoried in the definition phase and replaced or documented with an exit plan

Savings levers we measure against your baseline, and the controls your regulators expect

Lever or control	How it is measured or proven
Warehouse right-sizing and auto-suspend	Credits per workload before and after
Query and model optimisation for top spenders	Top 20 queries: runtime and credits
Storage and retention settings	Storage cost trend
Power BI refresh schedules	Capacity utilisation
EU-only processing, no foreign AI toolchain	Inventory and decision log (DORA ICT risk)
Change through your change board	Every guardrail as code, reviewed

Savings targets are set after the baseline. We do not quote % savings before measuring. AI-driven cost management example: Recordly's Virtual Data Engineer does cost and performance optimisation inside Snowflake (see team/vde); use only the facts in vde-facts.md.
