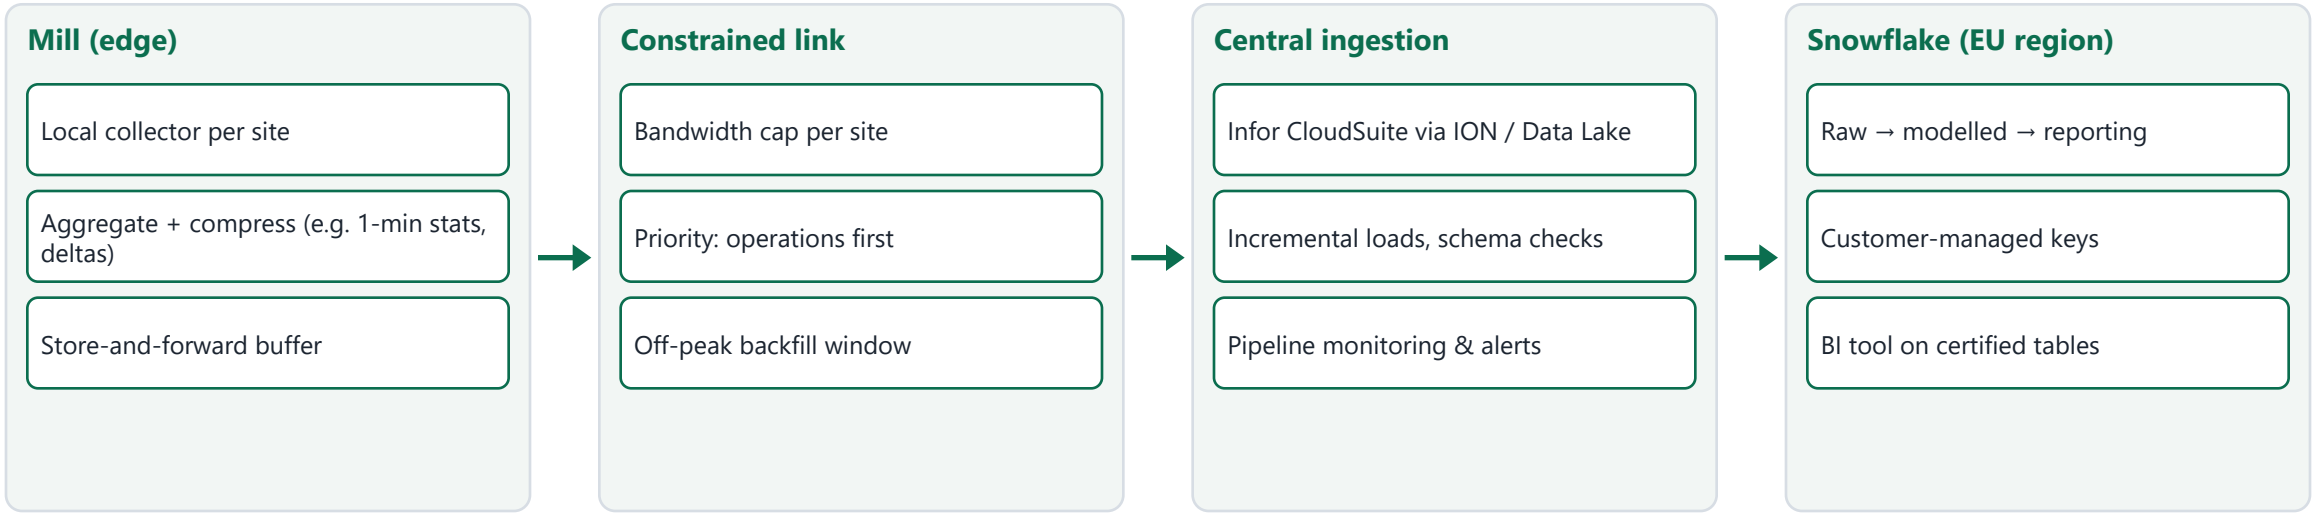
Valmet Oyj

# Tech & architecture slides for the Valmet deck

Two slides for deck-writer to insert after the answer-first slide

# Mill telemetry is summarised at the edge, so satellite links are never saturated

- Raw telemetry stays at the mill. Only aggregates and changes travel, under a bandwidth cap, and bulk backfills run off-peak.
- Infor CloudSuite and operational data land in Snowflake through the same monitored ingestion pattern.



Rollout one mill at a time: link usage is measured before and after, and the next site starts only if operations saw no impact

# We reduce foreign-jurisdiction exposure honestly: what can be controlled, and what cannot

| Measure | What it does | Limit we state openly |
|---|---|---|
| EU-region Snowflake account | Data stored and processed in the EU | Provider is US-headquartered |
| Customer-managed keys (Tri-Secret Secure) | Valmet can revoke access to the data | Needs Business Critical edition |
| Private connectivity, data minimisation | Only data needed for reporting leaves the mills | Design choice per data set |
| Open table format (Iceberg) for core data | Exit path to another platform | Migration effort if ever used |

Technical unknowns: link capacity per mill, Infor API limits, which data sets legal classifies as sensitive. Certifications on the proposed engineer: SnowPro Core and SnowPro Advanced: Data Engineer.
