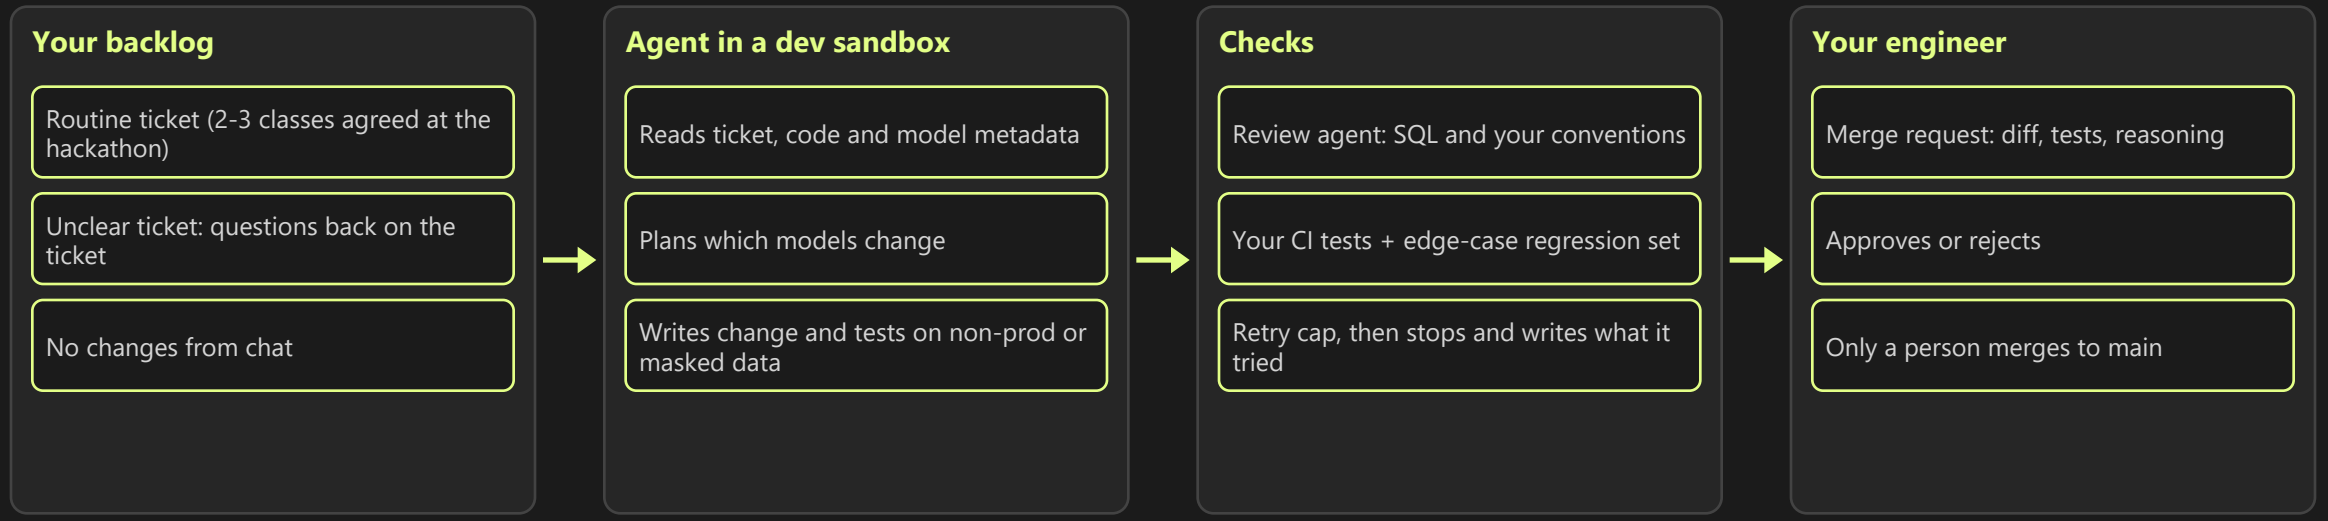
Sanoma

Tech & architecture slides for the Sanoma deck

Two slides: they replace the solution slide and the human-oversight slide, not added on top

The agent drafts in a sandbox; only your engineer can merge

- **Your stack, named after day 1.** The RFP says only "public cloud". If your warehouse is Snowflake with dbt, our running agent pattern deploys as is; otherwise the hackathon shows whether it ports, and you can stop.
- **Merge requests in your own tool.** Branch protection and required approval by your engineers: the agent has no merge right and no production credentials. Any engineer can pause it.
- **Not a black box.** Conventions, examples, prompts and the test set live in your repository; your engineers change the rules without us.



In your repository and cloud tenant: branch protection, no agent merge right, no production credentials, run log and cost cap per ticket, pause switch

Technical gates: you decide at each one, on numbers from your own tickets

Gate	When	Pass criterion
Access ready	Before hackathon day 1	Repository and merge-request access, a dev schema, 5-8 sample tickets; masking rules agreed if ticket or data samples hold personal data
Hackathon go/no-go	Week 1, day 2	Feasibility note: stack fit, routine share of the sample, edge cases found, access gaps, baseline lead time. Sanoma decides
Setup gate	End of week 3	Agent scored on 30-50 of your closed tickets, incl. the ones that "always go wrong"; pass share agreed with you after the first run, not before
Pilot, weekly	Weeks 4-16	Approved without rework, rejected and why, wrong passes, review minutes, lead time vs baseline. Any prompt, model or convention change replays the test set first

Technical unknowns, resolved on day 1: warehouse and transformation tool; Git and ticket host; share of the backlog that is routine; personal data in subscriber analytics. If the answer is "little routine work", we say so at the gate.
